

Assignment 3: Connectionist Architectures and Ensemble Techniques: Part 3

See our predictions file for the predictions. We derived our confidence estimate by finding the difference between the output and 0.5, and then multiplying by 2. If the output was closer to 1, we would be more confident that it is a male, and if the output was closer to 0 we would be more confident that it is a female. For example, an output of 0.9 would more likely to be a male than an output of 0.6.
